Relevant Reading for Today's Lecture

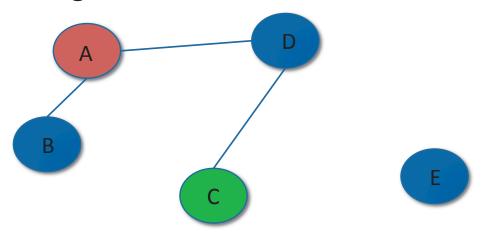

Section 12.2

Computational Models

- Programs that help us understand the world and solve practical problems
- Saw how we could map the informal problem of choosing what to eat into an optimization problem, and how we could design a program to solve it
- Now want to look at class of models called graphs

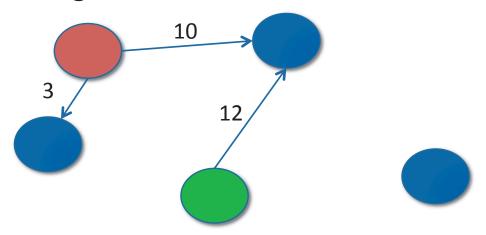

What's a Graph?

- Set of nodes (vertices)
 - Might have properties associated with them
- Set of edges (arcs) each consisting of a pair of nodes
 - Undirected (graph)
 - Directed (digraph)
 - Source (parent) and destination (child) nodes
 - Unweighted or weighted

What's a Graph?

- Set of nodes (vertices)
 - Might have properties associated with them
- Set of edges (arcs) each consisting of a pair of nodes
 - Undirected (graph)
 - Directed (digraph)
 - Source (parent) and destination (child) nodes
 - Unweighted or weighted

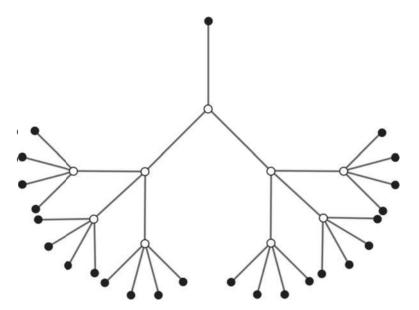

Why Graphs?

- To capture useful relationships among entities
 - Rail links between Paris and London
 - How the atoms in a molecule are related to one another
 - Ancestral relationships

Trees: An Important Special Case

- A special kind of directed graph in which any pair of nodes is connected by a single path
 - Recall the search trees we used to solve knapsack problem

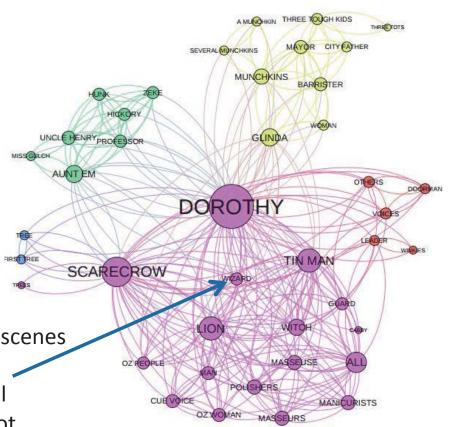

Why Graphs Are So Useful

- World is full of networks based on relationships
 - Computer networks
 - Transportation networks
 - Financial networks
 - Sewer or water networks
 - Political networks
 - Criminal networks
 - Social networks
 - Etc.

Analysis of "Wizard of Oz":

- size of node reflects number of scenes in which character shares dialogue

- color of clusters reflects natural interactions with each other but not others

Why Graphs Are So Useful

- We will see that not only do graphs capture relationships in connected networks of elements, they also support inference on those structures
 - Finding sequences of links between elements is there a path from A to B
 - Finding the least expensive path between elements (aka shortest path problem)
 - Partitioning the graph into sets of connected elements (aka graph partition problem)
 - Finding the most efficient way to separate sets of connected elements (aka the min-cut/max-flow problem)

Graph Theory Saves Me Time Every Day

Getting Eric to his Office

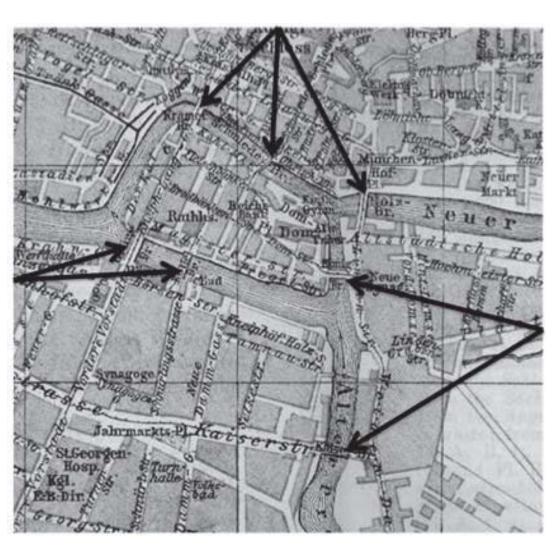

- •Model road system using a digraph
 - Nodes: points where roads end or meet
 - Edges: connections between points
 - Each edge has a weight
 - Expected time to get from source node to destination node for that edge
 - Distance between source and destination nodes
 - Average speed of travel between source and destination nodes
- Solve a graph optimization problem
 - Shortest weighted path between my house and my office

First Reported Use of Graph Theory

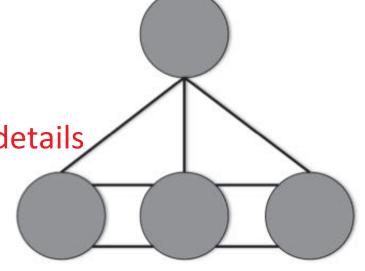

- Bridges of Königsberg (1735)
- Possible to take a walk that traverses each of the 7 bridges exactly once?

Map image © source unknown. All rights reserved. This content is excluded from our Creative Commons license. For more information, see https://ocw.mit.edu/help/faq-fair-use.

Leonhard Euler's Model

- Each island a node
- Each bridge an undirected edge
- Model abstracts away irrelevant details
 - Size of islands
 - Length of bridges

- •Is there a path that contains each edge exactly once?
 - No!

Implementing and using graphs

- Building graphs
 - Nodes
 - Edges
 - Stitching together to make graphs
- Using graphs
 - Searching for paths between nodes
 - Searching for optimal paths between nodes

Class Node

```
class Node(object):
    def __init__(self, name):
        """Assumes name is a string"""
        self.name = name
    def getName(self):
        return self.name
    def __str__(self):
        return self.name
```

Class Edge

Common Representations of Digraphs

- Digraph is a directed graph
 - Edges pass in one direction only
- Adjacency matrix
 - Rows: source nodes
 - Columns: destination nodes
 - Cell[s, d] = 1 if there is an edge from s to d= 0 otherwise
 - Note that in digraph, matrix is not symmetric
- Adjacency list
 - Associate with each node a list of destination nodes.

Class Digraph, part 1

```
class Digraph(object):
    """edges is a dict mapping each node to a list of
    its children"""
                                        Nodes are represented as
    def __init__(self):
                                         keys in dictionary
        se1f.edges = {}
    def addNode(self, node):
        if node in self.edges:
                                         Edges are represented by..
             raise ValueError('Duplicate node')
                                          destinations as values in list
        else:
                                           associated with a source key
             self.edges[node] = []
    def addEdge(self, edge):
        src = edge.getSource()
        dest = edge.getDestination()
        if not (src in self.edges and dest in self.edges):
             raise ValueError('Node not in graph')
        self.edges[src].append(dest)
```

Class Digraph, part 2

```
def childrenOf(self, node):
    return self.edges[node]
def hasNode(self, node):
    return node in self.edges
def getNode(self, name):
    for n in self.edges:
        if n.getName() == name:
            return n
    raise NameError(name)
def __str__(self):
    result = ''
    for src in self.edges:
        for dest in self.edges[src]:
            result = result + src.getName() + '->'\
                     + dest.getName() + '\n'
    return result[:-1] #omit final newline
```

Class Graph

```
class Graph(Digraph):
    def addEdge(self, edge):
        Digraph.addEdge(self, edge)
        rev = Edge(edge.getDestination(), edge.getSource())
        Digraph.addEdge(self, rev)
```

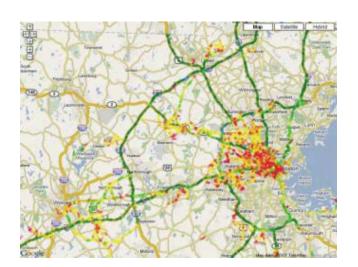

- Graph does not have directionality associated with an edge
 - Edges allow passage in either direction
- •Why is Graph a subclass of Digraph?
- •Remember the substitution rule?
 - If client code works correctly using an instance of the supertype, it should also work correctly when an instance of the subtype is substituted for the instance of the supertype
- Any program that works with a Digraph will also work with a Graph (but not vice versa)

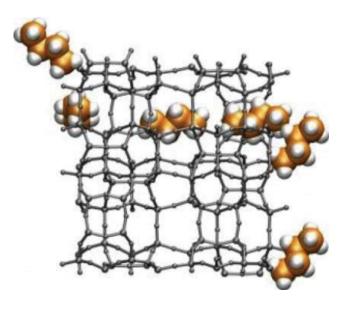

A Classic Graph Optimization Problem

- Shortest path from n1 to n2
 - Shortest sequence of edges such that
 - Source node of first edge is n1
 - Destination of last edge is n2
 - For edges, e1 and e2, in the sequence, if e2 follows e1 in the sequence, the source of e2 is the destination of e1
- Shortest weighted path
 - Minimize the sum of the weights of the edges in the path

Some Shortest Path Problems

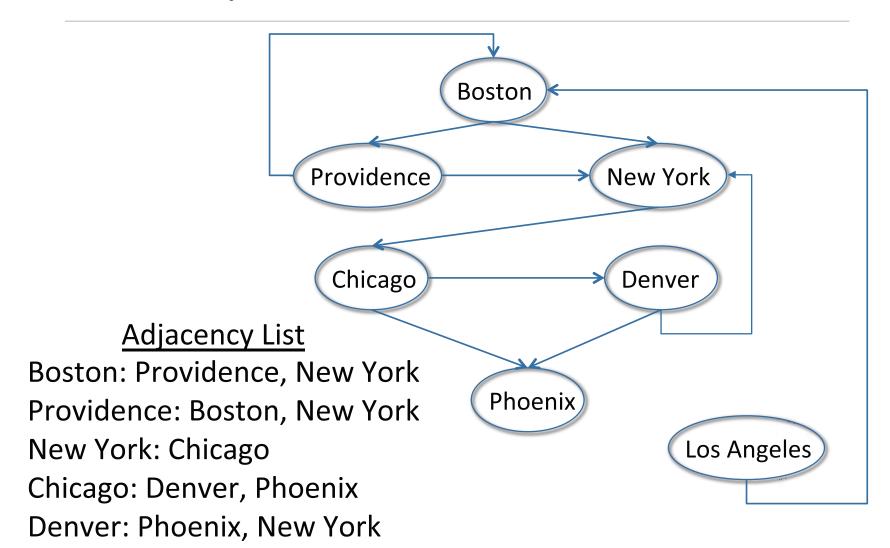

- Finding a route from one city to another
- Designing communication networks
- •Finding a path for a molecule through a chemical labyrinth

An Example

Phoenix:

Los Angeles: Boston

Build the Graph

Finding the Shortest Path

- Algorithm 1, depth-first search (DFS)
- Similar to left-first depth-first method of enumerating a search tree (Lecture 2)
- •Main difference is that graph might have cycles, so we must keep track of what nodes we have visited to avoid going in infinite loops

Note that we are using divide-and-conquer: if we can find a path from a source to an intermediate node, and a path from the intermediate node to the destination, the combination is a path from source to destination

Depth First Search

- Start at an initial node
- Consider all the edges that leave that node, in some order
- •Follow the first edge, and check to see if at goal node
 - If not, repeat the process from new node
 - Continue until either find goal node, or run out of options
 - When run out of options, backtrack to the previous node and try the next edge, repeating this process

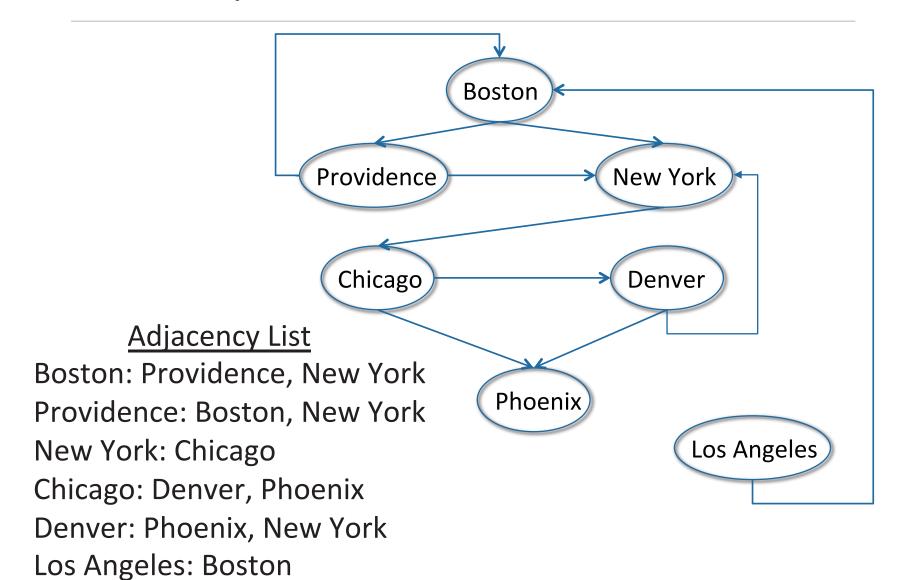

Depth First Search (DFS)

```
returning to this point in the
                                                       recursion to try next node
def DFS(graph, start, end, path, shortest, toPrint = False):
    path = path + [start]
                                                              Note how will explore
   if toPrint:
                                                               all paths through first
        print('Current DFS path:', printPath(path))
   if start == end:
                                                                node, before ...
        return path
   for node in graph.childrenOf(start):
        if node not in path: #avoid cycles
            if shortest == None or len(path) < len(shortest):
                newPath = DFS(graph, node, end, path, shortest, toPrint)
                if newPath != None:
                    shortest = newPath
        elif toPrint:
            print('Already visited', node)
    return shortest
def shortestPath(graph, start, end, toPrint = False):
    return DFS(graph, start, end, [], None, toPrint)
                                    Gets recursion started properly
       DFS called from a
       wrapper function:
                                     Provides appropriate abstraction
       shortestPath
```

Test DFS

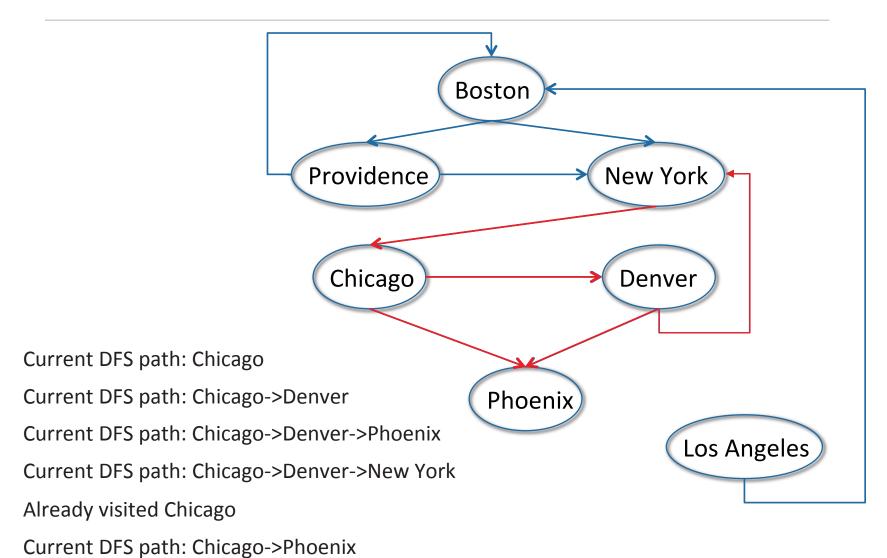

An Example

Phoenix:

Output (Chicago to Boston)

There is no path from Chicago to Boston

Output (Boston to Phoenix)

Current DFS path: Boston

Current DFS path: Boston->Providence

Already visited Boston

Current DFS path: Boston->Providence->New York

Current DFS path: Boston->Providence->New York->Chicago

Current DFS path: Boston->Providence->New York->Chicago->Denver

Current DFS path: Boston->Providence->New York->Chicago->Denver->Phoenix Found path

Already visited New York

Current DFS path: Boston->Providence->New York->Chicago->Phoenix Found a shorter path

Current DFS path: Boston->New York

Current DFS path: Boston->New York->Chicago

Current DFS path: Boston->New York->Chicago->Denver

Current DFS path: Boston->New York->Chicago->Denver->Phoenix Found a "shorter" path

Already visited New York

Current DFS path: Boston->New York->Chicago->Phoenix Found a shorter path

Shortest path from Boston to Phoenix is Boston->New York->Chicago->Denver->Phoenix

Breadth First Search

- Start at an initial node
- Consider all the edges that leave that node, in some order
- •Follow the first edge, and check to see if at goal node
- If not, try the next edge from the current node
- Continue until either find goal node, or run out of options
 - When run out of edge options, move to next node at same distance from start, and repeat
 - When run out of node options, move to next level in the graph (all nodes one step further from start), and repeat

Algorithm 2: Breadth-first Search (BFS)

```
def BFS(graph, start, end, toPrint = False):
    initPath = [start]
    pathQueue = [initPath]
    while len(pathQueue) != 0:
        #Get and remove oldest element in pathQueue
        tmpPath = pathQueue.pop(0)
        if toPrint:
            print('Current BFS path:', printPath(tmpPath))
        lastNode = tmpPath[-1]
        if lastNode == end:
            return tmpPath ←
        for nextNode in graph.childrenOf(lastNode):
            if nextNode not in tmpPath:
                newPath = tmpPath + [nextNode]
                pathQueue.append(newPath)
    return None
```

Explore all paths with n hops before exploring any path with more than n hops

Output (Boston to Phoenix)

Current BFS path: Boston

Current BFS path: Boston->Providence

Current BFS path: Boston->New York

Current BFS path: Boston->Providence->New York

Current BFS path: Boston->New York->Chicago

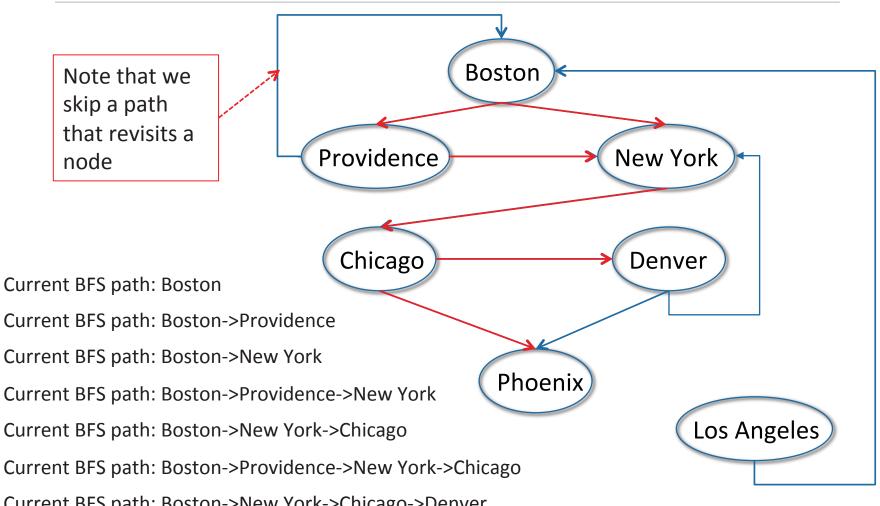

Current BFS path: Boston->Providence->New York->Chicago

Current BFS path: Boston->New York->Chicago->Denver

Current BFS path: Boston->New York->Chicago->Phoenix

Shortest path from Boston to Phoenix is Boston->New York->Chicago->Phoenix

Output (Boston to Pheonix)

Current BFS path: Boston->New York->Chicago->Denver

Current BFS path: Boston->New York->Chicago->Phoenix

Shortest path from Boston to Phoenix is Boston->New York->Chicago->Phoenix

What About a Weighted Shortest Path

- •Want to minimize the sum of the weights of the edges, not the number of edges
- DFS can be easily modified to do this
- BFS cannot, since shortest weighted path may have more than the minimum number of hops

Recap

- Graphs are cool
 - Best way to create a model of many things
 - Capture relationships among objects
 - Many important problems can be posed as graph optimization problems we already know how to solve
- Depth-first and breadth-first search are important algorithms
 - Can be used to solve many problems
